## Description

bitest performs exact hypothesis tests for binomial random variables. The null hypothesis is that the probability of a success on a trial is $\#_{p}$. The total number of trials is the number of nonmissing values of varname (in bitest) or $\#_{N}$ (in bitesti). The number of observed successes is the number of 1 s in varname (in bitest) or $\#_{\text {succ }}$ (in bitesti). varname must contain only $0 \mathrm{~s}, 1 \mathrm{~s}$, and missing.
bitesti is the immediate form of bitest; see [U] 19 Immediate commands for a general introduction to immediate commands.

## Quick start

Exact test for probability of success $(a=1)$ is 0.4
bitest a = . 4
With additional exact probabilities
bitest a = .4, detail
Exact test that the probability of success is 0.46 , given 22 successes in 74 trials
bitesti 7422.46

## Menu

bitest
Statistics $>$ Summaries, tables, and tests $>$ Classical tests of hypotheses $>$ Binomial probability test

## bitesti

Statistics $>$ Summaries, tables, and tests $>$ Classical tests of hypotheses $>$ Binomial probability test calculator

## Syntax

Binomial probability test
bitest varname $=\#_{p}$ [if] [in] [weight] [, detail]

Immediate form of binomial probability test
bitesti $\#_{N} \#_{\text {succ }} \#_{p}[$, detail $]$
by and collect are allowed with bitest; see [U] 11.1.10 Prefix commands.
fweights are allowed with bitest; see [U] 11.1.6 weight.

## Option

## Remarks and examples

Remarks are presented under the following headings:
bitest
bitesti

## bitest

> Example 1
We test 15 university students for high levels of one measure of visual quickness which, from other evidence, we believe is present in $30 \%$ of the nonuniversity population. Included in our data is quick, taking on the values 1 ("success") or 0 ("failure") depending on the outcome of the test.

```
. use https://www.stata-press.com/data/r18/quick
. bitest quick == 0.3
Binomial probability test
\begin{tabular}{r|rrrrr} 
Variable & N & Observed \(k\) & Expected \(k\) & Assumed p & Observed p \\
\hline quick & 15 & 7 & 4.5 & 0.30000 & 0.46667
\end{tabular}
    Pr(k >= 7) = 0.131143 (one-sided test)
    Pr}(\textrm{k}<=7)=0.949987 (one-sided test
    Pr}(\textrm{k}<=1\mathrm{ or k >= 7) = 0.166410 (two-sided test)
```

The first part of the output reveals that, assuming a true probability of success of 0.3 , the expected number of successes is 4.5 and that we observed seven. Said differently, the assumed frequency under the null hypothesis $H_{0}$ is 0.3 , and the observed frequency is 0.47 .

The first line under the table is a one-sided test; it is the probability of observing seven or more successes conditional on $p=0.3$. It is a test of $H_{0}: p=0.3$ versus the alternative hypothesis $H_{\mathrm{A}}: p>0.3$. Said in English, the alternative hypothesis is that more than $30 \%$ of university students score at high levels on this test of visual quickness. The $p$-value for this hypothesis test is 0.13 .

The second line under the table is a one-sided test of $H_{0}$ versus the opposite alternative hypothesis $H_{\mathrm{A}}: p<0.3$.

The third line is the two-sided test. It is a test of $H_{0}$ versus the alternative hypothesis $H_{\mathrm{A}}: p \neq 0.3$.

## Technical note

The $p$-value of a hypothesis test is the probability (calculated assuming $H_{0}$ is true) of observing any outcome as extreme or more extreme than the observed outcome, with extreme meaning in the direction of the alternative hypothesis. In example 1 , the outcomes $k=8,9, \ldots, 15$ are clearly "more extreme" than the observed outcome $k_{\text {obs }}=7$ when considering the alternative hypothesis $H_{\mathrm{A}}: p \neq 0.3$. However, outcomes with only a few successes are also in the direction of this alternative hypothesis. For two-sided hypotheses, outcomes with $k$ successes are considered "as extreme or more extreme" than the observed outcome $k_{\text {obs }}$ if $\operatorname{Pr}(k) \leq \operatorname{Pr}\left(k_{\text {obs }}\right)$. Here $\operatorname{Pr}(k=0)$ and $\operatorname{Pr}(k=1)$ are both less than $\operatorname{Pr}(k=7)$, so they are included in the two-sided $p$-value.

The detail option allows you to see the probability (assuming that $H_{0}$ is true) of the observed successes $(k=7)$ and the probability of the boundary point $(k=1)$ of the opposite tail used for the two-sided $p$-value.

```
. bitest quick == 0.3, detail
Binomial probability test
\begin{tabular}{c|ccccr} 
Variable & \multicolumn{1}{c}{N} & Observed k & Expected k & Assumed p & Observed p \\
\hline quick & 15 & 7 & 4.5 & 0.30000 & 0.46667 \\
\(\operatorname{Pr}(\mathrm{k}>=7)\) & \(=0.131143\) & (one-sided test) & & \\
\(\operatorname{Pr}(\mathrm{k}\langle=7)\) & \(=0.949987\) & (one-sided test) & \\
\(\operatorname{Pr}(\mathrm{k}\langle=1\) or \(\mathrm{k}>=7)\) & \(=0.166410\) & (two-sided test) & \\
\(\operatorname{Pr}(\mathrm{k}==7)\) & \(=0.081130\) & (observed) & \\
\(\operatorname{Pr}(\mathrm{k}==2)\) & \(=0.091560\) & & \\
\(\operatorname{Pr}(\mathrm{k}==1)\) & \(=0.030520\) & (opposite extreme) &
\end{tabular}
```

Also shown is the probability of the point next to the boundary point. This probability, namely, $\operatorname{Pr}(k=2)=0.092$, is certainly close to the probability of the observed outcome $\operatorname{Pr}(k=7)=0.081$, so some people might argue that $k=2$ should be included in the two-sided $p$-value. Statisticians (at least some we know) would reply that the $p$-value is a precisely defined concept and that this is an arbitrary "fuzzification" of its definition. When you compute exact $p$-values according to the precise definition of a $p$-value, your type I error is never more than what you say it is -so no one can criticize you for being anticonservative. Including the point $k=2$ is being overly conservative because it makes the $p$-value larger yet. But it is your choice; being overly conservative, at least in statistics, is always safe. Know that bitest and bitesti always keep to the precise definition of a $p$-value, so if you wish to include this extra point, you must do so by hand or by using the r() stored results; see Stored results below.

## bitesti

## Example 2

The binomial test is a function of two statistics and one parameter: $N$, the number of observations; $k_{\text {obs }}$, the number of observed successes; and $p$, the assumed probability of a success on a trial. For instance, in a city of $N=2,500,000$, we observe $k_{\text {obs }}=36$ cases of a particular disease when the population rate for the disease is $p=0.00001$.

## Stored results

bitest and bitesti store the following in $r()$ :
Scalars

```
r(N) number }N\mathrm{ of trials
    r(P_p) assumed probability p of success
    r(k) observed number k of successes
    r(p_l) lower one-sided p-value
    r(p_u) upper one-sided p-value
    r(p) two-sided p-value
    r(k_opp) opposite extreme k
    r(P_k) probability of observed k (detail only)
    r(P_oppk) probability of opposite extreme k (detail only)
    r(k_nopp) b next to opposite extreme (detail only)
    r(P_noppk) probability of k next to opposite extreme (detail only)
```

## Methods and formulas

Let $N, k_{\text {obs }}$, and $p$ be, respectively, the number of observations, the observed number of successes, and the assumed probability of success on a trial. The expected number of successes is $N p$, and the observed probability of success on a trial is $k_{\text {obs }} / N$.
bitest and bitesti compute exact $p$-values based on the binomial distribution. The upper one-sided $p$-value is

$$
\operatorname{Pr}\left(k \geq k_{\mathrm{obs}}\right)=\sum_{m=k_{\mathrm{obs}}}^{N}\binom{N}{m} p^{m}(1-p)^{N-m}
$$

The lower one-sided $p$-value is

$$
\operatorname{Pr}\left(k \leq k_{\mathrm{obs}}\right)=\sum_{m=0}^{k_{\mathrm{obs}}}\binom{N}{m} p^{m}(1-p)^{N-m}
$$

If $k_{\text {obs }} \geq N p$, the two-sided $p$-value is

$$
\operatorname{Pr}\left(k \leq k_{\mathrm{opp}} \text { or } k \geq k_{\mathrm{obs}}\right)
$$

where $k_{\text {opp }}$ is the largest number $\leq N p$ such that $\operatorname{Pr}\left(k=k_{\text {opp }}\right) \leq \operatorname{Pr}\left(k=k_{\text {obs }}\right)$. If $k_{\text {obs }}<N p$, the two-sided $p$-value is

$$
\operatorname{Pr}\left(k \leq k_{\mathrm{obs}} \text { or } k \geq k_{\mathrm{opp}}\right)
$$

where $k_{\text {opp }}$ is the smallest number $\geq N p$ such that $\operatorname{Pr}\left(k=k_{\text {opp }}\right) \leq \operatorname{Pr}\left(k=k_{\text {obs }}\right)$.
